**WORKING  
PAPER  
(WITH  
ABSTRACT)**

**“Anti-Black Hate Crimes & Health Outcomes of Black Americans”**

Black-White disparities in health are well documented. While earlier scholarship has often connected these disparities to gaps in socio-economic status, recent work demonstrates that higher income is not consistently protective against worse health outcomes. This paper points to a factor beyond socio-economic status that may be important for generating racial disparities in health. Anti-Black hate crimes have been rising in recent years, and exposure to race-motivated violence is likely disproportionately stressful for Black Americans. I conduct two separate but complementary studies that document the adverse impact of anti-Black hate crimes on the health outcomes of Black infants and adults. In the first study, I leverage restricted-access nation-wide birth records from the National Center for Health Statistics to show that in utero exposure to local anti-Black aggravated assaults is associated with lower birth weights and shorter gestation lengths among Black infants. In the second study, I use restricted-access Emergency Department Data from the California Department of Health Care Access and Information and find an increase in the volume of chest pain-related Emergency Department visits among Black adults in the days that follow an anti-Black aggravated assault in their area of residence. Throughout both studies, I report that the effects on White infants and adults are negligible in magnitude and largely insignificant. This suggests that stress associated with exposure to local anti-Black hate crimes may be contributing to the racial health disparities present in the United States. In summary, this paper provides novel evidence for policymakers and relevant stakeholders actively advocating for the importance of efforts to mitigate hate crimes.
